PRODUCT CHARACTERISTICS:
In swine, Dectomax is formulated to deliver the recommended dosage of body weight when given by subcutaneous (SC) or intramuscular (IM) route. In young (less than 12 months) animals, the dosage may need to be increased to achieve the desired treatment. The product is not expected to have an adverse impact on populations of dung-dependent species when used according to label directions, but if used in areas where dung-dependent species are present, the parasite management plan should be adjusted accordingly.

RESIDUE WARNINGS:
No treatment withdrawal period is required for Dectomax in cattle. Cattle should be treated 7 days prior to the estimated end of the fly season or before anticipated high fly pressure. All treated cattle should be removed from feedlots and holdback areas for at least 14 days after the last treatment (end of fly season).
